

Variants of Gödel's Ontological Proof in a Natural Deduction Calculus

Annika Kanckos · Bruno Woltzenlogel Paleo

the date of receipt and acceptance should be inserted later

Abstract This paper presents detailed formalizations of ontological arguments in a simple modal natural deduction calculus. The first formal proof closely follows the hints in Scott's manuscript about Gödel's argument and fills in the gaps, thus verifying its correctness. The second formal proof improves the first one, by relying on the weaker modal logic **KB** instead of the stronger modal logic **S5**; and by avoiding the equality relation. The second proof is also technically shorter than the first one, because it eliminates unnecessary detours and uses Axiom 1 for the positivity of properties only once. The third and fourth proofs formalize, respectively, Anderson's and Bjørdal's variants of the ontological argument, which are known to be immune to modal collapse.

Keywords: Ontological Argument, Higher-Order Logics, Modal Logics, Natural Deduction.

“There is a scientific (exact) philosophy and theology, which deals with concepts of the highest abstractness; and this is also most highly fruitful for science. [...] Religions are, for the most part, bad; but religion is not.”
- Kurt Gödel (*Wang*, 1996)[p. 316]

1 Introduction

Ontological arguments for the existence of God can be traced back at least to St. Anselm (1033-1109). His argument considers a greatest conceivable being, who must exist, because if it did not have the property of existence, then we could conceive of a greater being that, in addition to other properties, also had the property of existence. St. Anselm's argument was criticized and further developed by Descartes, Leibniz and Kant, among many others.

Leibniz identified the possible existence of God as a critical missing step in St. Anselm’s argument. To fill this gap, he argued that the properties of God, the perfections, are compatible. This means that it is possible to satisfy all perfections at once, which implies that the existence of a greatest conceivable being with all these properties is possible.

Gödel built on Leibniz’s work (Adams, 1995) and brought the ontological argument to a modern form using a modal logic with higher-order quantification over properties. In this setting, he gave precise axioms describing the notion of *positive* property and defined God as a being that has all positive properties. Gödel’s work was saved in his own notes (Gödel, 1970) as well as in notes by Scott (Scott, 2001), to whom he confided his proof.

The increase in formality of the ontological argument has required a development of its basic notions. Gödel’s notion of positive property and Leibniz’s notion of perfection differ. A formal distinction is that Leibniz’s perfections are atomic whereas Gödel’s positive properties can consist of combinations of atomic properties (Fitting, 2002)[p.139]. In particular, one of Gödel’s axioms states that any conjunction of positive properties is itself positive. From this axiom, it is immediately deduced that the property of being God-like is positive. Intuitively, a (possibly infinite) conjunction of positive properties is deduced from the universal definition of God-likeness. This deductive inference is not formalizable in a finite first-order calculus. The interplay between universal quantification (in the definition of a God-like being) and infinite conjunctions (in Gödel’s axiom for positive properties) could explain why, starting with Scott (Scott, 2001), this axiom of Gödel has been replaced by another that simply assumes the positivity of the property of being god-like.

The aim of this paper is to present detailed formalizations of variants of ontological arguments in a natural deduction calculus. For a comprehensive introduction to natural deduction, the reader can consult (Prawitz, 2006) or (Gabbay, 1996). The natural deduction calculus proposed and used in this paper is an extension of a standard natural deduction calculus for (non-modal) higher-order logic (Benzmüller & Brown & Kohlhase, 2004) with new introduction and elimination rules for modal operators (as presented in Section 2). This calculus is sound and complete relative to the non-modal calculus extended with Axiom K and the Necessitation rule (as demonstrated in Subsection 2.1). There are many higher-order logics (Benzmüller & Brown & Kohlhase, 2004) and higher-order modal logics (Muskens, 2006). The calculus proposed here can be regarded as a minimalistic calculus for a rigid higher-order modal logic K without extensionality principles. With additional axioms for stronger modal logics, such as KB and S5, this calculus is sufficient to achieve the stated aim.

The natural deduction style was chosen for four reasons. Firstly, presentations of Gödel’s proof are typically either informal or formalized in other styles of proof calculi (e.g. Fitting’s tableaux (Fitting, 2002) or Sobel’s sentential modal calculus (Sobel, 2001)). Therefore, a formalization in natural deduction is a valuable complement to the existing presentations. Secondly, it makes the ontological proof accessible to people who are familiarized with the natural deduction style. Thirdly, as natural deduction is the style used by proof assistants such as Coq (Paulin-Mohring, 2015) and Isabelle (Nipkow & Paulson & Wenzel, 2002), natural deduction formalizations can be verified step-by-step in such proof assistants, and we have in fact done this (Benzmüller & Woltzenlogel Paleo, 2015a). And finally, in comparison to other kinds of proof systems (e.g. resolution, tableaux, sequent calculi), natural deduction can be considered less technical, more human-readable and more intuitive, because it relies on natural principles of reasoning such as modus ponens (implication elimination) and reasoning by assumption (implication introduction); these qualities are conducive to rendering the formalizations of ontological arguments accessible to a wider audience.

The first main contribution of this paper is a detailed formalization of Scott’s version (Scott, 2001) of Gödel’s ontological argument (Gödel, 1970) (as shown in Section 4) in the proposed natural deduction calculus. The second main contribution of the paper is a new proof (shown in Section 5), also in natural deduction style. In contrast to Scott’s proof (Scott, 2001), which requires the modal logic **S5**, the new proof requires only the weaker modal logic

KB. The new proof also does not rely on the equality relation and is much shorter. Although there have been claims (as discussed in more detail in Section 5) about the sufficiency of **KB** and the superfluosity of the equality relation, formal proofs substantiating these claims were missing up to now.

A major criticism against Gödel’s argument is an undesirable consequence of the stipulated axioms called *modal collapse*. This is discussed in greater detail in Section 6, where a natural deduction derivation of the collapse is presented. Many recent works on the ontological argument have proposed modifications of the argument that do not entail modal collapse. In this paper we present natural deduction formalizations of two of these solutions: Anderson’s emendation (in Section 7) and Bjørdal’s variant (in Section 8).

1.1 Related Work

An early unpublished draft of Section 5 of this paper, prepared by Woltzenlogel Paleo in March 2013, served as the starting point for two distinct but complementary research endeavours. Siders and Woltzenlogel Paleo transformed that early draft into this paper, aiming for human-readable and yet formal natural deduction proofs. Benz Müller and Woltzenlogel Paleo, on the other hand, focused on the verification of variants of Gödel’s ontological arguments using higher-order automated reasoning tools, which quickly led to many publications. The main automatically obtained results about Gödel’s and Scott’s proofs appeared in the European Conference on Artificial Intelligence (*Benz Müller & Woltzenlogel Paleo, 2014d*) and, two years later, a detailed analysis of an inconsistency found in Gödel’s axioms was published in the International Joint Conference on Artificial Intelligence (*Benz Müller & Woltzenlogel Paleo, 2016a*). The automatic verification of variants by Anderson, Bjørdal and Hájek were presented in the First World Congress on Logic and Religion (*Benz Müller & Weber & Woltzenlogel Paleo, 2015*) and published in (*Benz Müller & Weber & Woltzenlogel Paleo, 2016*) and results related to the modal collapse were reported in the 4th Word Congress on the Square of Opposition (*Benz Müller & Woltzenlogel Paleo, 2014c*) and later published in (*Benz Müller & Woltzenlogel Paleo, 2016b*). More detailed reconstructions of Scott’s variant within the interactive proof assistants Isabelle and Coq were released, respectively, in Isabelle’s Archive of Formal Proofs (*Benz Müller & Woltzenlogel Paleo, 2013b*) and in the Symposium of Computer Science in Russia (*Benz Müller & Woltzenlogel Paleo, 2015a*). The popularity of the topic led to invited talks and corresponding invited abstracts in the proceedings of workshops (*Benz Müller & Woltzenlogel Paleo, 2014a,b, 2013a*) and summer schools (*Benz Müller & Woltzenlogel Paleo, 2015c,b*) as well as articles targeting a more general audience (*Woltzenlogel Paleo, 2013*). More recently, this line of research ventured into other types of ontological arguments, and a computer-assisted reconstruction of an argument by Leibniz will appear as a chapter in a book dedicated to the 300th anniversary of Leibniz’s death (*Bentert & Benz Müller & Streit & Woltzenlogel Paleo, 2016*). The automatic verification of Gödel’s and Scott’s variants (*Benz Müller & Woltzenlogel Paleo, 2014d*) was preceded by an automatic verification of (a non-modal version of) Anselm’s ontological argument (*Oppenheimer & Zalta, 2011*). However, whereas the complexity of Gödel’s and Scott’s arguments required the embedding of higher-order modal logics into higher-order logics and the use of higher-order automated reasoners, Anselm’s argument greater simplicity enabled its verification with a first-order prover. Anselm’s argument has also been formalized within the interactive proof assistant PVS (*Rushby, 2013*) and there has been a failed attempt to formalize Avicenna’s argument in PVS as well.

2 Natural Deduction

The language of higher-order modal logic used here is inspired by that of Church’s simple type theory (*Church, 1940*).

Definition 1 *Simple types* are given by the following grammar:

$$\theta, \tau ::= \mu \mid o \mid \theta \rightarrow \tau$$

where μ is the atomic type for individuals, o is the atomic type for propositions and $\theta \rightarrow \tau$ is the type for functions taking an argument of type θ and returning something of type τ . ‘ \rightarrow ’ is assumed to be right associative.

Definition 2 *Terms and formulas* are given by the following grammar:

$$\begin{aligned} s, t ::= & p_\tau \mid X_\tau \mid (\lambda X_\theta. s_\tau)_{\theta \rightarrow \tau} \mid (s_{\theta \rightarrow \tau} t_\theta)_\tau \mid \\ & \perp_o \mid \rightarrow_{o \rightarrow o \rightarrow o} \mid \wedge_{o \rightarrow o \rightarrow o} \mid \\ & \forall_{(\tau \rightarrow o) \rightarrow o} \mid \exists_{(\tau \rightarrow o) \rightarrow o} \mid \Box_{o \rightarrow o} \mid \Diamond_{o \rightarrow o} \end{aligned}$$

where p_τ and X_τ range over, respectively, constants and variables of type τ . Parenthesis conventions, infix notation for propositional connectives and binding notation¹ for quantifiers are assumed. Furthermore, subscript types are omitted when they are clear from the context. Implicit alpha-conversion is assumed: two expressions are considered to be the same modulo renaming of their bound variables. Negation ($\neg_{o \rightarrow o}$), disjunction ($\vee_{o \rightarrow o \rightarrow o}$), equivalence ($\leftrightarrow_{o \rightarrow o \rightarrow o}$), equality ($=_{\tau \rightarrow \tau \rightarrow o}$), inequality ($\neq_{\tau \rightarrow \tau \rightarrow o}$), are defined by $\neg A \equiv A \rightarrow \perp$, $(A \vee B) \equiv \neg(\neg A \wedge \neg B)$, $(A \leftrightarrow B) \equiv (A \rightarrow B) \wedge (B \rightarrow A)$, $s = t \equiv \forall P.(P s) \leftrightarrow (P t)$ (Leibniz’s equality) and $s \neq t \equiv \neg(s = t)$, .

The natural deduction calculus proposed and used here has standard rules for propositional connectives and quantifiers, as shown in Figures 1 and 4. The extension to classical logic is achieved by adding a rule for double negation elimination, shown in Figure 3, and β -reduction² is handled by the β rule shown in Figure 5. Finally, modal operators are handled by special new rules that insert or remove formulas from boxes, as shown in Figure 6. A *derivation* is a directed acyclic graph whose nodes are formulas and whose edges correspond to applications of the inference rules. A *proof* of a formula F is a derivation without open assumptions and having F as root not inside any box.

In every inference rule, (sub-)formulas in the conclusion correspond³ to formulas in the premises (even in the case of quantifier rules, where the formulas differ due to substitution). For any expression occurring both in a formula in the premise and in its corresponding (sub-) formula in the conclusion, the occurrence in the premise is said to be an *ancestor* of the occurrence in the conclusion, and the occurrence in the conclusion is said to be a *descendant* of the occurrence in the premise.

Applications of the β rule are silently omitted. Double lines are used to abbreviate propositional reasoning steps when they are tedious and too space-consuming. Dashed lines are used to refer to an axiom or theorem with the proof shown elsewhere. When proof trees are too large to fit on the page, some branches may be displayed separately. In such cases, the conclusion of the branch and the location in the main proof tree where the branch belongs are annotated with the same symbol (a subscripted \star). Dotted lines are used to indicate folding and unfolding of definitions. Furthermore, as it is inconvenient to draw boxes around large derivations in L^AT_EX, formulas inside boxes are labeled with the names of the boxes surrounding them. Therefore, the boxes can be omitted without loss of information.

The calculus having only the rules shown in Figures 1, 3, 4 and 5 is named **ND**. This calculus is essentially the same as the simplest natural deduction calculus in the family of calculi discussed in (Benzmüller & Brown & Kohlhase, 2004). The main difference is that they take disjunction as a primitive connective instead of conjunction, and they use a sequent notation, where the assumptions are listed in the left side of the sequent. The calculus with the new rules for modal operators shown in Figure 6 is named **ND_K**.

¹ $\forall x.F[x]$ and $\exists x.F[x]$ are assumed to be abbreviations for, respectively, $\forall(\lambda x.F[x])$ and $\exists(\lambda x.F[x])$.

² Rules for η -expansion (Benzmüller & Brown & Kohlhase, 2004) are not included here, because they are not needed in the ontological arguments studied here.

³ This correspondence could be defined formally, but it would be tedious to do so.

Fig. 1 Propositional rules

$$\begin{array}{cccc}
\frac{\perp}{A} \perp_E & \frac{B}{A \rightarrow B} \rightarrow_I & \frac{\overline{A}^n \vdots B}{A \rightarrow B} \rightarrow_I^n & \frac{A \quad A \rightarrow B}{B} \rightarrow_E \\
\frac{A \quad B}{A \wedge B} \wedge_I & \frac{A \wedge B}{A} \wedge_{E1} & \frac{A \wedge B}{B} \wedge_{E2} &
\end{array}$$

Fig. 2 Admissible propositional rules

$$\frac{\neg A \quad A}{\perp} \neg_E \quad \frac{A \leftrightarrow B \quad B}{A} \leftrightarrow_E \quad \frac{A \leftrightarrow B \quad A}{B} \leftrightarrow_E$$

Fig. 3 Double negation elimination

$$\frac{\neg\neg A}{A} \neg\neg_E$$

Fig. 4 Quantifier rules

$$\begin{array}{cccc}
\frac{A[\alpha]}{\forall x_\tau. A[x]} \forall_I & \frac{\forall x_\tau. A[x]}{A[t]} \forall_E & \frac{A[t]}{\exists x_\tau. A[x]} \exists_I & \frac{\exists x_\tau. A[x]}{A[\beta]} \exists_E
\end{array}$$

eigen-variable conditions:

if ρ is a \forall_I inference eliminating a variable α , then any occurrence of α in the proof should be an ancestor of the occurrence of α eliminated by ρ and not a descendant of a variable introduced by a \exists_E inference;

if ρ is a \exists_E inference introducing a variable β , then any occurrence of β in the proof should be a descendant of the occurrence of β introduced by ρ and not an ancestor of a variable eliminated by a \forall_I inference.

Fig. 5 Reduction rules

$$\frac{A}{B} \beta$$

only if B and A are β -equivalent
(i.e. there is a C such that both B and A β -reduce to C)

2.1 Suitability for Rigid Higher-Order Modal Logic K

ND is a calculus for a (non-modal) higher-order logic without functional and boolean extensionality principles (*Benzmüller & Brown & Kohlhase, 2004*). Adding the modal rules results in a calculus that is suitable for a basic rigid modal logic **K**, in the sense that **ND_K** is sound and complete relative to **ND** extended with axiom K ($\Box(A \rightarrow B) \rightarrow (\Box A \rightarrow \Box B)$) and the necessitation rule (which establishes that $\Box A$ is a theorem if A is a theorem).

Theorem 1 ***ND_K** is complete relative to **ND** extended with axiom K and necessitation.*

Fig. 6 Rules for modal operators

Proof The necessitation rule can be immediately simulated with the \Box_I rule. Axiom K can be derived in **ND_K** as shown below:

$$\frac{\frac{\frac{}{\Box(A \rightarrow B)} 2}{\omega : A \rightarrow B} \Box_E \quad \frac{\frac{}{\Box A} 1}{\omega : A} \Box_E}{\frac{\omega : B}{\Box B} \Box_I} \rightarrow_E \quad \frac{\frac{\Box A \rightarrow \Box B}{\Box A \rightarrow \Box B} \rightarrow_I^1}{\Box(A \rightarrow B) \rightarrow (\Box A \rightarrow \Box B)} \rightarrow_I^2$$

Theorem 2 **ND_K** is sound relative to **ND** extended with axiom K and necessitation.

Proof It is necessary to show that **ND_K** proofs of the following form can be translated to proofs in **ND** extended with the axiom K and the necessitation rule.

$$\frac{\frac{\frac{\Box A_1}{\omega : A_1} \Box_E \quad \frac{\Box A_n}{\omega : A_n} \Box_E}{\vdots \quad \dots \quad \vdots} \quad \frac{\omega : B}{\Box B} \Box_I$$

A translation to **ND** extended with axiom K and necessitation is shown below for the case when $n = 1$:

$$\frac{\frac{\frac{\frac{}{A_1} 1}{B} \rightarrow_I^1}{\Box(A_1 \rightarrow B)} \text{ necessitation} \quad \frac{\text{Axiom K}}{\Box(A_1 \rightarrow B) \rightarrow (\Box A_1 \rightarrow \Box B)}}{\frac{\Box A_1 \rightarrow \Box B}{\Box B} \rightarrow_E} \rightarrow_E \quad \Box A_1 \rightarrow_E$$

For $n > 1$, the translation is a straightforward generalization:

$$\begin{array}{c}
\frac{}{A_1} 1 \quad \frac{}{A_n} n \\
\vdots \quad \dots \quad \vdots \\
\frac{B}{A_1 \rightarrow \dots \rightarrow A_n \rightarrow B} \xrightarrow{I^*} \\
\frac{}{\Box(A_1 \rightarrow \dots \rightarrow A_n \rightarrow B)} \text{ nec.} \quad \frac{\text{Axiom K, iterated}}{\Box(A_1 \rightarrow \dots \rightarrow A_n \rightarrow B) \rightarrow (\Box A_1 \rightarrow \dots \rightarrow \Box A_n \rightarrow \Box B)} \\
\hline
\Box A_1 \rightarrow \dots \rightarrow \Box A_n \rightarrow \Box B \xrightarrow{E} \\
\hline
\frac{\Box A_1 \rightarrow \dots \rightarrow \Box A_n \rightarrow \Box B}{\Box B} \xrightarrow{E}
\end{array}$$

Without the restriction that every box must be accessed by exactly one strong modal inference, the calculus would be unsound for the modal logic **K**. For example, the formula $\forall \phi.(\Box \phi \rightarrow \Diamond \phi)$ is not valid in **K** but would be provable without this restriction:

$$\begin{array}{c}
\frac{}{\Box \phi} 1 \\
\frac{}{\omega : \phi} \Box_E \\
\frac{}{\Diamond \phi} \Diamond_I \\
\frac{}{\Box \phi \rightarrow \Diamond \phi} \rightarrow_I^1 \\
\frac{}{\forall \phi.(\Box \phi \rightarrow \Diamond \phi)} \forall_I
\end{array}$$

This example proof is unsound according to the **ND_K** calculus, because the eigen-box condition is violated: the box labelled by ω is not accessed by any strong inference.

The straightforward combinations of the quantifier rules of **ND** either with the modal rules of **ND_K** or with axiom K and the necessitation rule are suitable for a higher-order modal logic where constants and variables are *rigid*. From the point of view of a *possible world semantics*, rigidity means that their interpretation is independent of the world in which they are being interpreted. Rigidity is tacitly assumed by most works investigating the ontological argument, and is explicitly assumed here. Nevertheless, it should be noted that its adequacy for the ontological argument has already been contested (*Fitting*, 2002). Another assumption made here is that the quantification domains are constant (i.e. independent of the possible worlds). Neither Gödel's manuscript nor Scott's manuscript reveal whether they use constant or varying domains, and this is also the case for many variants (e.g. *Hajek* 1996). Nevertheless, some authors of variants of Gödel's ontological argument do explicitly state a preference for varying domains. Our choice of constant domains is motivated by simplicity (*Anderson*, 1990, footnotes 11 and 14). As is well-known, varying domain quantifiers (also known as *actualistic* quantifiers) can be simulated by constant domain quantifiers (also known as *possibilistic* quantifiers) guarded by a primitive *existence* predicate⁴; therefore, the formalization of ontological arguments with varying domain quantification would be feasible in the natural deduction calculus presented here as well.

3 Some Useful Derivable Principles

From an axiomatic point of view, modal logics stronger than **K** differ from each other with respect to which axiom schemas they admit in addition to K (and necessitation). Some common axiom schemas of relevance to the ontological argument are T ($\Box A \rightarrow A$), B ($A \rightarrow \Box \Diamond A$), 4 ($\Box A \rightarrow \Box \Box A$) and 5 ($\Diamond A \rightarrow \Box \Diamond A$). From a semantic point of view, these axioms correspond to geometric frame conditions that must be satisfied by the accessibility relation in Kripke models (see e.g. *Fitting & Mendelsohn* 1998 or *Blackburn & al.* 2001, Section 3.1 on Frame definability): T corresponds to reflexivity, B corresponds to symmetry, 4 corresponds to transitivity and 5 corresponds to euclidianity. In the models of logic **S5**, all these axioms are satisfied; in the models of logic **KB**, B is satisfied; and in the models of logic **B**, T and B are satisfied.

⁴ Formally, $\forall^e x. F[x] \equiv \forall x. E(x) \rightarrow F[x]$ and $\exists^e x. F[x] \equiv \exists x. E(x) \wedge F[x]$.

Proof

$$\begin{array}{c}
\text{Brouwer's Reduction} \\
\frac{\omega : \Diamond \Box A \rightarrow A}{\Box(\Diamond \Box A \rightarrow A)} \Box_I \quad \frac{\Box(\Diamond \Box A \rightarrow A) \rightarrow (\Box \Diamond \Box A \rightarrow \Box A)}{\Box \Diamond \Box A \rightarrow \Box A} K \rightarrow_E \quad \frac{\text{Axiom 5 for } \Box A}{\Diamond \Box A \rightarrow \Box \Diamond \Box A} \quad \frac{\Box \Diamond \Box A}{\Box \Diamond \Box A} 1 \rightarrow_E \\
\hline
\frac{\Box A}{\Diamond \Box A \rightarrow \Box A} \rightarrow_I^1
\end{array}$$

The *reflexivity* of equality is a theorem in higher-order logics where equality is defined as Leibniz's equality. A natural deduction proof can be easily constructed, as shown below.

Lemma (Reflexivity)

$$\forall x. x = x$$

Proof

$$\begin{array}{c}
\frac{\frac{P(\alpha)}{P(\alpha) \rightarrow P(\alpha)} \rightarrow_I^1 \quad \frac{P(\alpha)}{P(\alpha) \rightarrow P(\alpha)} \rightarrow_I^2}{(P(\alpha) \rightarrow P(\alpha)) \wedge (P(\alpha) \rightarrow P(\alpha))} \wedge_I \\
\frac{\dots}{P(\alpha) \leftrightarrow P(\alpha)} \\
\frac{P(\alpha) \leftrightarrow P(\alpha)}{\forall P. P(\alpha) \leftrightarrow P(\alpha)} \forall_I \\
\frac{\dots}{\alpha = \alpha} \\
\frac{\alpha = \alpha}{\forall x. x = x} \forall_I
\end{array}$$

4 Scott's Proof in Natural Deduction

In this section we present a detailed formalization of Scott's proof in the natural deduction calculus defined in Section 2. The reasoning in Scott's manuscript has been reproduced step-by-step and reasoning gaps are completed by using the deduction steps considered most natural. All derived formulas that do appear in Scott's manuscript are marked with a \dagger here. Unmarked formulas were derived in the process of filling the gaps between the marked formulas.

Scott's version of Gödel's proof depends on five axioms that circumscribe the notion of *positive* property, with positivity being denoted by the undefined second-order predicate symbol P . Additionally, three definitions are used for establishing the notions of *God-like*, *essence* and *necessary existence*. Technically, these definitions only abbreviate certain complex formulas. The argument would still go through if all defined symbols were replaced by the complex formulas they define. This observation is particularly relevant in the case of *necessary existence*. Since this notion of "existence" is just an abbreviation, Gödel's argument is not susceptible to Kant's criticism against Anselm's argument (that existence should not be treated as a predicate). In Gödel's proof, existence is properly denoted by the existential quantifier. It is, therefore, unfortunately misleading to refer to the defined predicate symbol E as "necessary existence", when in fact it is just a convenient abbreviation.

In addition to the five axioms and three definitions that pertain specifically to the argument, the proof also uses **S5**'s iteration principle (in the proof of Lemma 2) and the lemma of reflexivity for equality (in the proof of Theorem 1). The use of reflexivity could be avoided, but we chose to use it because it allows the construction of a shorter proof.

Axiom 1 *Either a property or its negation is positive, but not both:*

$$\forall \varphi. (P(\neg \varphi) \leftrightarrow \neg P(\varphi))$$

Axiom 2 *A property necessarily implied by a positive property is positive:*

$$\forall \varphi. \forall \psi. ((P(\varphi) \wedge \Box \forall x. (\varphi(x) \rightarrow \psi(x))) \rightarrow P(\psi))$$

Proof

$$\begin{array}{c}
\frac{\frac{\frac{\overline{\exists z.G(z)}}{1} \exists_E}{G(\gamma)} \quad \frac{\frac{\overline{\forall x.G(x) \rightarrow G \text{ ess } x}}{\forall_E} \quad \frac{\frac{\overline{G(\gamma) \rightarrow G \text{ ess } \gamma}}{\rightarrow_E} \quad \frac{\overline{G \text{ ess } \gamma^\dagger}}{G \text{ ess } \gamma^\dagger}}{\rightarrow_E} \quad \frac{\frac{\overline{\forall \varphi.P(\varphi) \rightarrow \varphi(\gamma)}}{\forall_E} \quad \frac{\frac{\overline{P(E) \rightarrow E(\gamma)}}{\rightarrow_E} \quad \frac{\overline{E(\gamma)^\dagger}}{E(\gamma)^\dagger}}{\rightarrow_E} \quad \frac{\frac{\overline{\forall \varphi.\varphi \text{ ess } \gamma \rightarrow \Box \exists x.\varphi(x)}}{\forall_E} \quad \frac{\overline{G \text{ ess } \gamma \rightarrow \Box \exists x.G(x)}}{\rightarrow_E}}{\rightarrow_E} \quad \frac{\overline{\Box \exists x.G(x)}}{\Box \exists x.G(x)} \rightarrow_I^1 \\
\frac{\overline{\exists z.G(z) \rightarrow \Box \exists x.G(x)}}{\exists z.G(z) \rightarrow \Box \exists x.G(x)} \rightarrow_I^1
\end{array}$$

Lemma 2 *If the existence of a God-like being is possible, then it is necessary:*

$$\Diamond \exists z.G(z) \rightarrow \Box \exists x.G(x)$$

Proof

$$\begin{array}{c}
\frac{\frac{\frac{\overline{\omega : \exists x.G(x) \rightarrow \Box \exists x.G(x)}}{\Box_I} \quad \frac{\overline{\Box(\exists x.G(x) \rightarrow \Box \exists x.G(x))}}{\Box_I} \quad \frac{\overline{\Diamond \exists x.G(x) \rightarrow \Diamond \Box \exists x.G(x)}}{\rightarrow_E} \quad \frac{\overline{\Diamond \Box \exists x.G(x)^\dagger}}{\Diamond \Box \exists x.G(x)^\dagger}}{\rightarrow_E} \quad \frac{\overline{\Box \exists x.G(x)}}{\Box \exists x.G(x)} \rightarrow_I^1 \\
\frac{\overline{\Diamond \exists x.G(x)}}{\Diamond \exists x.G(x)} \rightarrow_I^1 \quad \frac{\overline{\Diamond \Box \exists x.G(x) \rightarrow \Box \exists x.G(x)}}{\Diamond \Box \exists x.G(x) \rightarrow \Box \exists x.G(x)} \rightarrow_E
\end{array}$$

Theorem 3 *Necessarily, there exists a God-like being:*

$$\Box \exists x.G(x)$$

Proof

$$\frac{\frac{\overline{\Diamond \exists x.G(x)}}{\Diamond \exists x.G(x)} \quad \frac{\overline{\Diamond \exists x.G(x) \rightarrow \Box \exists x.G(x)}}{\Diamond \exists x.G(x) \rightarrow \Box \exists x.G(x)} \rightarrow_E}{\Box \exists x.G(x)}$$

5 A New Proof

In this section we present a new proof in **KB**. This proof uses exactly the same axioms and definitions of Scott's proof shown in the previous sections, but it uses neither the axiom of reflexivity for equality nor **S5**'s modal iteration principle. Instead, it relies only on Brouwer's reduction principle (for Theorem 3). The new proof is also shorter than Scott's proof.

Axiom 1 *Either a property or its negation is positive, but not both:*

$$\forall \varphi.(P(\neg \varphi) \leftrightarrow \neg P(\varphi))$$

Axiom 2 *A property necessarily implied by a positive property is positive:*

$$\forall \varphi.\forall \psi.((P(\varphi) \wedge \Box \forall x.(\varphi(x) \rightarrow \psi(x))) \rightarrow P(\psi))$$

Theorem 1 *Positive properties are possibly exemplified:*

$$\forall \varphi.(P(\varphi) \rightarrow \Diamond \exists x.\varphi(x))$$

Proof

$$\begin{array}{c}

\end{array}$$

Comparing this new proof of Theorem 1 with the proof of Theorem 1 indicated by Gödel and Scott, it is noticeable that the new proof is significantly shorter. The key idea to obtain a shorter proof is to instantiate the second universally quantified property of Axiom 2 by $\lambda x. \neg \rho(x)$ instead of using the relation symbols $=$ or \neq as Gödel and Scott did. This eliminates the reliance of the ontological argument on the presence of $=$ and \neq in the logical language. Furthermore, Axiom 2 is then needed only once.

Although the simpler proof of Theorem 1 presented here was developed independently, it seems conceptually related to a possible simplification briefly described by Anderson (Anderson, 1990, footnote 2) and attributed by him to an anonymous referee. The simpler proof of Theorem 1 is not particularly special. In fact, it is probably the most likely proof that any well-trained logician would construct, if asked to derive Theorem 1 from Axioms 1 and 2 using methodical formal proof search techniques. Modern techniques usually rely on unification to compute or guess good instances for weakly quantified variables, and therefore they would never result in instantiations containing $=$ and \neq , which are symbols that do not appear anywhere in the axioms or in the theorems to be proved. We may wonder why Gödel preferred to use those unusual instantiations. It might be an interesting question from a historical point of view, as it might suggest that there was an evolution in the way logicians construct formal proofs; or from a philosophical point of view, if Gödel's preference was philosophically motivated.

Definition 1 A *God-like* being possesses all positive properties:

$$G(x) \equiv \forall \varphi. (P(\varphi) \rightarrow \varphi(x))$$

Axiom 3 The property of being god-like is positive:

$$P(G)$$

Corollary 1 Possibly, a God-like being exists:

$$\Diamond \exists x. G(x)$$

Proof The proof of this corollary is identical to the proof shown in Section 4.

Axiom 4 Positive properties are necessarily positive:

$$\forall \varphi. (P(\varphi) \rightarrow \Box P(\varphi))$$

$\varphi \text{ ess } x \equiv \varphi(x) \wedge \forall \psi.(\psi(x) \rightarrow \Box \forall x.(\varphi(x) \rightarrow \psi(x)))$

At this point, Gödel and Scott proceed to prove Theorem 2, which is then used to prove Lemma 1. However, a close inspection of Scott's proof of Lemma 1 reveals that Theorem 2 is an unnecessary detour. Therefore, we do not include it in the new proof.

Definition 3 *Necessary existence* of an individual is the necessary exemplification of all its essences:

$$E(x) \equiv \forall \varphi.(\varphi \text{ ess } x \rightarrow \Box \exists y.\varphi(y))$$
$$P(E)$$

This phenomenon is intriguing: the new proof of Lemma 1 is technically simpler (because it has fewer inferences), but Scott’s proof of Lemma 1 with Theorem 2 can be considered intuitively simpler (because it is easier to understand). This constitutes an interesting case for Hilbert’s 24th Problem (Thiele, 2003), which asks for criteria to properly compare the simplicity of proofs. While Hilbert had mathematical proofs in mind, insights into the 24th problem could be gained by analyzing philosophical proofs as well. As Gödel suggested, “a scientific (exact) philosophy [...] is also most highly fruitful for science”.

$$\exists z.G(z) \rightarrow \Box \exists x.G(x)$$
[illegible]

hence actuality, possibility and necessity coincide (*Sobel*, 2001)[Ch. 4, section 6, theorems 9 and 10]. That is: for all propositions A ,

$$A \Leftrightarrow \Diamond A \Leftrightarrow \Box A$$

Below we show natural deduction derivations of the modal collapse, thereby confirming that it holds⁵ for the axioms used in the previous sections. We show only the strongest implication above. The others are easy corollaries in modal logics where T holds.

Theorem 4 *For all propositions A , the following modal collapse proposition is provable:*

[illegible]

In Gödel's ontological proof, we are proving a restricted modal collapse, which applies to one specific formula, the existence of a God-like being. The interest in the proof naturally decreases if a consequence of the axiomatization is a modal collapse for *all* formulas. Therefore, an improvement would be obtained if the modal collapse was limited only to the property of being god-like or at least to a restricted collection of properties. Several solutions to the problem of modal collapse have been proposed. Fitting, for instance, has argued that greater care has to be taken with the semantics of higher-order modal logics. Quantified variables may be rigid or flexible; and properties may be treated as intensional or extensional. Making the right choices may prevent the modal collapse (*Fitting*, 2002, Sections 11.9 and 11.10). Koons (*Koons*, 2006), Anderson (*Anderson*, 1990, p. 292) and Sobel (*Sobel*, 2001, p. 133) also discuss the idea that the notion of property over which quantification is allowed might be too general and restrictions might be appropriate. Two alternative and more conservative solutions, requiring only modifications of the axioms and definitions but no change in the logic, are discussed in greater detail in the next sections.

7 Anderson's Emendation in Natural Deduction

Anderson's solution (*Anderson*, 1990) modifies the definitions of God-like being and essence, and eliminates half of Axiom 1 (replacing the equivalence by an implication).

Axiom 1 (Emended) *If the negation of a property is positive, the property is not positive:*

$$\forall \varphi. (P(\neg \varphi) \rightarrow \neg P(\varphi))$$

⁵ It is well-known and uncontroversial that the modal collapse holds. We show a natural deduction proof here merely for the sake of self-containment and so that the proof becomes more accessible to readers who might be more familiarized with natural deduction than with Sobel's proof system.

Axiom 2 (As in Scott's) *A property necessarily implied by a positive property is positive:*

$$\forall\varphi.\forall\psi.((P(\varphi) \wedge \Box\forall x.(\varphi(x) \rightarrow \psi(x))) \rightarrow P(\psi))$$

Theorem 1 *Positive properties are possibly exemplified:*

$$\forall\varphi.(P(\varphi) \rightarrow \Diamond\exists x.\varphi(x))$$

Proof This proof is omitted, because any of the proofs of Theorem 1 in Sections 4 and 5 would suffice to prove this theorem with only a small modification: the equivalence of axiom 1 would not need to be reduced to an implication by conjunction elimination.

Definition 1 (Emended) A *God-like* being necessarily possesses those and only those properties which are positive:

$$G(x) \equiv \forall\varphi.(P(\varphi) \leftrightarrow \Box\varphi(x))$$

Axiom 3 (As in Scott's) *The property of being god-like is positive:*

$$P(G)$$

Corollary 1 *Possibly, a God-like being exists:*

$$\Diamond\exists x.G(x)$$

Proof This proof is omitted, because it is identical to the proof of the same corollary shown in Sections 4 and 5.

Axiom 4 (As in Scott's) *Positive properties are necessarily positive:*

$$\forall\varphi.(P(\varphi) \rightarrow \Box P(\varphi))$$

Definition 2 (Emended) An *essence* of an individual is a property possessed by it and necessarily implying those and only those properties necessarily possessed by it:

$$\varphi \text{ ess } x \equiv \varphi(x) \wedge \forall\psi.(\Box\psi(x) \leftrightarrow \Box\forall x.(\varphi(x) \rightarrow \psi(x)))$$

Definition 3 (As in Scott's) *Necessary existence* of an individual is the necessary exemplification of all its essences:

$$E(x) \equiv \forall\varphi.(\varphi \text{ ess } x \rightarrow \Box\exists y.\varphi(y))$$

Axiom 5 (As in Scott's) *Necessary existence is a positive property:*

$$P(E)$$

Because of Anderson's emendations to Axiom 1 and Definition 1, the proof of Lemma 1 has to be modified as well. The proof shown below uses the modal axiom T to eliminate the extra box modality introduced by Anderson in his emended Definition 1.

Lemma 1 *If there is a God-like being, then there is a God-like being necessarily:*

$$\exists z.G(z) \rightarrow \Box\exists x.G(x)$$

Proof

$$\frac{\frac{}{\exists z.G(z)} 1}{[\star_9] \quad G(\gamma)} \exists_E$$

18

7.1 A Shorter Proof without Superfluous Axioms

In order to construct a natural deduction proof of theorem 3 using only Anderson's axioms 1, 2 and 3 as well as Anderson's Definition 1, it suffices to modify the proof of Lemma 1, which is the only part of the argument that depended on axioms 4 and 5 and definitions 2 and 3. The modified proof is shown below.

Lemma 1 *If there is a God-like being, then there is a God-like being necessarily:*

$$\exists z.G(z) \rightarrow \Box \exists x.G(x)$$

Proof

$$\frac{\frac{\frac{\overline{\exists z.G(z)} \quad 2}{G(\gamma)} \exists_E \quad \frac{\overline{\forall \varphi.(P(\lambda x.\varphi(x)) \leftrightarrow \Box \varphi(\gamma))} \quad \text{D1}}{P(G) \leftrightarrow \Box G(\gamma)} \forall_E \quad \frac{\text{Axiom 3}}{P(G)} \rightarrow_E}{\Box G(\gamma)} \frac{\frac{\frac{\overline{G(\gamma)} \quad 1}{\exists x.G(x)} \exists_I \quad \frac{G(\gamma) \rightarrow \exists x.G(x)}{\Box(G(\gamma) \rightarrow \exists x.G(x))} \rightarrow_I^1 \quad \frac{\Box(G(\gamma) \rightarrow \exists x.G(x))}{\Box G(\gamma) \rightarrow \Box \exists x.G(x)} \Box_I}{\Box G(\gamma) \rightarrow \Box \exists x.G(x)} \text{(Axiom K)} \rightarrow_E \rightarrow_I^2 \frac{\Box \exists x.G(x)}{\exists z.G(z) \rightarrow \Box \exists x.G(x)}$$

Proofs of other lemmas, theorems and corollaries remain the same as in the previous section. Theorem 1 is derived from axioms 1 and 2. Corollary 1 is derived from Axiom 3 and Theorem 1. Finally, Theorem 3 can be derived from Corollary 1 and Lemma 1, which, as shown above, depends only on Axiom 3 and Definition 1. Therefore, confirming Hájek's claim, axioms 4 and 5 and definitions 2 and 3 are superfluous: they are not needed to prove Theorem 3.

7.2 A Proof-Theoretical Explanation for the Immunity to Modal Collapse

Anderson's change in the definition of essence adds an extra box modality, which transforms the standard proof (shown in Section 6) of modal collapse (i.e. $\vdash A \rightarrow \Box A$) into a proof of a tautology ($\vdash \Box A \rightarrow \Box A$), as shown below.

$$\frac{\frac{\frac{\overline{\overline{\forall y.(G(y) \rightarrow G(y) \wedge \forall \psi.(\Box \psi(y) \leftrightarrow \Box \forall x.(G(x) \rightarrow \psi(x)))}} \quad \text{Theorem 2}}{\overline{\forall y.(G(y) \rightarrow G(y) \wedge \forall \psi.(\Box \psi(y) \leftrightarrow \Box \forall x.(G(x) \rightarrow \psi(x)))}} \quad \text{D2}}{\overline{\forall y.(G(y) \rightarrow \forall \psi.(\Box \psi(y) \leftrightarrow \Box \forall x.(G(x) \rightarrow \psi(x)))}} \quad \text{D2}}{\overline{\forall y.(G(y) \rightarrow (\Box A \leftrightarrow \Box \forall x.(G(x) \rightarrow A))}} \quad \text{D2}}{\overline{[\star_{13}] \quad \exists y.G(y) \rightarrow (\Box A \leftrightarrow \Box \forall x.(G(x) \rightarrow A))}} \quad \text{D2}}{\frac{\frac{\frac{\overline{\overline{\exists y.G(y) \rightarrow (\Box A \leftrightarrow \Box \forall x.(G(x) \rightarrow A))}} \quad \star_{13}}{\Box A \leftrightarrow \Box \forall x.(G(x) \rightarrow A)} \rightarrow_E \quad \frac{\frac{\overline{\overline{\Box \exists y.G(y)}} \quad \text{Theorem 3}}{\Box \exists y.G(y)} \Box_E}{\Box A \leftrightarrow \Box (\exists x.G(x) \rightarrow A)} \rightarrow_E \quad \frac{\overline{\Box A} \quad 1}{\Box A \leftrightarrow \Box A} \leftrightarrow_E \quad \frac{\overline{\omega : \exists x.G(x) \rightarrow A}}{\omega : \exists x.G(x)} \Box_E \quad \frac{\overline{\omega : \exists x.G(x) \rightarrow A}}{\omega : \exists x.G(x)} \Box_E \quad \frac{\overline{\omega : A} \quad \Box_I}{\Box A \rightarrow \Box A} \rightarrow_I^1 \rightarrow_I^1$$

The exchange of the implication in Scott's definition of essence for an equivalence and the additional necessitation (box) modality before the property ψ (which is instantiated by $\lambda x.A$) prevents the implication of a necessary fact from its contingent counterpart, as seen in the second part of the proof above, because the hypothetical assumption of the contingent property A has to be exchanged for its necessitation $\Box A$ to preserve the proof structure.

Corollary 1 *Possibly, a God-like being exists:*

$$\Diamond \exists x. G(x)$$

$$\begin{array}{c}
\text{Proof} \quad \frac{\frac{\overline{\Box \forall x.(G_B(x) \rightarrow G_B(x))}}{\dots\dots\dots} \text{D1} \quad \frac{\text{Theorem 1}}{P_B(G_B) \rightarrow \Diamond \exists x.G_B(x)} \wedge_I \\
\frac{P_B(G_B)}{\dots\dots\dots} \rightarrow_E \\
\Diamond \exists x.G_B(x)
\end{array}$$

Lemma 1 *If there is a God-like being, then there is a God-like being necessarily:*

$$\exists z.G_B(z) \rightarrow \Box \exists x.G_B(x)$$

Proof

[illegible]

9 Conclusions

The formal proofs presented here are short and accessible because of the choice of a natural deduction calculus. The new proof of section 5 shows explicitly that the weaker modal logic **KB** is sufficient for the ontological argument. The stronger modal logic **S5**, which is usually taken for granted in discussions of Gödel's ontological argument, is not necessary. This weakening of the underlying logic confirms a claim briefly mentioned by Anderson (*Anderson*, 1990, footnote 2). **KB** is also sufficient for the variants of Anderson and Bjørdal, which address Sobel's criticism of the modal collapse.
